## Chapter 1

## Spectral Theorems in Euclidean and Hermitian Spaces

### 1.1 Normal Linear Maps

Let $E$ be a real Euclidean space (or a complex Hermitian space) with inner product $u, v \mapsto\langle u, v\rangle$.

In the real Euclidean case, recall that $\langle-,-\rangle$ is bilinear, symmetric and positive definite (i.e., $\langle u, u\rangle>0$ for all $u \neq 0)$.

In the complex Hermitian case, recall that $\langle-,-\rangle$ is sesquilinear, which means that it linear in the first argument, semilinear in the second argument (i.e.,
$\langle u, \mu v\rangle=\bar{\mu}\langle u, v\rangle),\langle v, u\rangle=\overline{\langle u, v\rangle}$, and positive definite (as above).

In both cases we let $\|u\|=\sqrt{\langle u, u\rangle}$ and the map $u \mapsto\|u\|$ is a norm.

Recall that every linear map, $f: E \rightarrow E$, has an adjoint $f^{*}$ which is a linear map, $f^{*}: E \rightarrow E$, such that

$$
\langle f(u), v\rangle=\left\langle u, f^{*}(v)\right\rangle
$$

for all $u, v \in E$.

Since $\langle-,-\rangle$ is symmetric, it is obvious that $f^{* *}=f$.
Definition 1.1.1 Given a Euclidean (or Hermitian) space, $E$, a linear map $f: E \rightarrow E$ is normal iff

$$
f \circ f^{*}=f^{*} \circ f
$$

A linear map $f: E \rightarrow E$ is self-adjoint if $f=f^{*}$, skew self-adjoint if $f=-f^{*}$, and orthogonal if $f \circ f^{*}=f^{*} \circ f=\mathrm{id}$.

Our first goal is to show that for every normal linear map $f: E \rightarrow E$ (where $E$ is a Euclidean space), there is an orthonormal basis (w.r.t. $\langle-,-\rangle$ ) such that the matrix of $f$ over this basis has an especially nice form:

It is a block diagonal matrix in which the blocks are either one-dimensional matrices (i.e., single entries) or twodimensional matrices of the form

$$
\left(\begin{array}{cc}
\lambda & \mu \\
-\mu & \lambda
\end{array}\right)
$$

This normal form can be further refined if $f$ is self-adjoint, skew self-adjoint, or orthogonal.

As a first step, we show that $f$ and $f^{*}$ have the same kernel when $f$ is normal.

Lemma 1.1.2 Given a Euclidean space E, if $f: E \rightarrow E$ is a normal linear map, then
Ker $f=\operatorname{Ker} f^{*}$.

The next step is to show that for every linear map $f: E \rightarrow E$, there is some subspace $W$ of dimension 1 or 2 such that $f(W) \subseteq W$.

When $\operatorname{dim}(W)=1, W$ is actually an eigenspace for some real eigenvalue of $f$.

Furthermore, when $f$ is normal, there is a subspace $W$ of dimension 1 or 2 such that $f(W) \subseteq W$ and $f^{*}(W) \subseteq W$.

The difficulty is that the eigenvalues of $f$ are not necessarily real. One way to get around this problem is to complexify both the vector space $E$ and the inner product $\langle-,-\rangle$.

First, we need to embed a real vector space $E$ into a complex vector space $E_{\mathbb{C}}$.

A fancy way to define $E_{\mathbb{C}}$ is to use tensor products and to set

$$
E_{\mathbb{C}}=\mathbb{C} \otimes_{\mathbb{R}} E
$$

However, we can also define $E_{\mathbb{C}}$ directly as follows:

Definition 1.1.3 Given a real vector space $E$, let $E_{\mathbb{C}}$ be the structure $E \times E$ under the addition operation

$$
\left(u_{1}, u_{2}\right)+\left(v_{1}, v_{2}\right)=\left(u_{1}+v_{1}, u_{2}+v_{2}\right)
$$

and multiplication by a complex scalar $z=x+i y$ defined such that

$$
(x+i y) \cdot(u, v)=(x u-y v, y u+x v)
$$

It is easily shown that the structure $E_{\mathbb{C}}$ is a complex vector space.

It is also immediate that

$$
(0, v)=i(v, 0)
$$

and thus, identifying $E$ with the subspace of $E_{\mathbb{C}}$ consisting of all vectors of the form $(u, 0)$, we can write

$$
(u, v)=u+i v
$$

Given a vector $w=u+i v$, its conjugate $\bar{w}$ is the vector $\bar{w}=u-i v$.

Given a linear map $f: E \rightarrow E$, the map $f$ can be extended to a linear map $f_{\mathbb{C}}: E_{\mathbb{C}} \rightarrow E_{\mathbb{C}}$ defined such that

$$
f_{\mathbb{C}}(u+i v)=f(u)+i f(v)
$$

Next, we need to extend the inner product on $E$ to an inner product on $E_{\mathbb{C}}$.

The inner product $\langle-,-\rangle$ on a Euclidean space $E$ is extended to the Hermitian positive definite form $\langle-,\rangle_{\mathbb{C}}$ on $E_{\mathbb{C}}$ as follows:

$$
\begin{aligned}
\left\langle u_{1}+i v_{1}, u_{2}\right. & \left.+i v_{2}\right\rangle_{\mathbb{C}} \\
& =\left\langle u_{1}, u_{2}\right\rangle+\left\langle v_{1}, v_{2}\right\rangle+i\left(\left\langle u_{2}, v_{1}\right\rangle-\left\langle u_{1}, v_{2}\right\rangle\right)
\end{aligned}
$$

Then, given any linear map $f: E \rightarrow E$, it is easily verified that the map $f_{\mathbb{C}}^{*}$ defined such that

$$
f_{\mathbb{C}}^{*}(u+i v)=f^{*}(u)+i f^{*}(v)
$$

for all $u, v \in E$, is the adjoint of $f_{\mathbb{C}}$ w.r.t. $\langle-,-\rangle_{\mathbb{C}}$.

Assuming again that $E$ is a Hermitian space, observe that Lemma 1.1.2 also holds.

Lemma 1.1.4 Given a Hermitian space E, for any normal linear map $f: E \rightarrow E$, a vector $u$ is an eigenvector of $f$ for the eigenvalue $\lambda$ (in $\mathbb{C}$ ) iff $u$ is an eigenvector of $f^{*}$ for the eigenvalue $\bar{\lambda}$.

The next lemma shows a very important property of normal linear maps: eigenvectors corresponding to distinct eigenvalues are orthogonal.

Lemma 1.1.5 Given a Hermitian space E, for any normal linear map $f: E \rightarrow E$, if $u$ and $v$ are eigenvectors of $f$ associated with the eigenvalues $\lambda$ and $\mu$ (in $\mathbb{C}$ ) where $\lambda \neq \mu$, then $\langle u, v\rangle=0$.

We can also show easily that the eigenvalues of a selfadjoint linear map are real.

Lemma 1.1.6 Given a Hermitian space E, the eigenvalues of any self-adjoint linear map $f: E \rightarrow E$ are real.

Given any subspace $W$ of a Hermitian space $E$, recall that the orthogonal $W^{\perp}$ of $W$ is the subspace defined such that

$$
W^{\perp}=\{u \in E \mid\langle u, w\rangle=0, \text { for all } w \in W\} .
$$

Recall that $E=W \oplus W^{\perp}$ (construct an orthonormal basis of $E$ using the Gram-Schmidt orthonormalization procedure). The same result also holds for Euclidean spaces.

The following lemma provides the key to the induction that will allow us to show that a normal linear map can diagonalized. It actually holds for any linear map.

Lemma 1.1.7 Given a Hermitian space E, for any linear map $f: E \rightarrow E$, if $W$ is any subspace of $E$ such that $f(W) \subseteq W$ and $f^{*}(W) \subseteq W$, then $f\left(W^{\perp}\right) \subseteq W^{\perp}$ and $f^{*}\left(W^{\perp}\right) \subseteq W^{\perp}$.

The above Lemma also holds for Euclidean spaces. Although we are ready to prove that for every normal linar map $f$ (over a Hermitian space) there is an orthonormal basis of eigenvectors, we now return to real Euclidean spaces.

If $f: E \rightarrow E$ is a linear map and $w=u+i v$ is an eigenvector of $f_{\mathbb{C}}: E_{\mathbb{C}} \rightarrow E_{\mathbb{C}}$ for the eigenvalue $z=\lambda+i \mu$, where $u, v \in E$ and $\lambda, \mu \in \mathbb{R}$, since

$$
f_{\mathbb{C}}(u+i v)=f(u)+i f(v)
$$

and

$$
\begin{aligned}
f_{\mathbb{C}}(u+i v)=(\lambda+i \mu)(u+i v) & \\
& =\lambda u-\mu v+i(\mu u+\lambda v)
\end{aligned}
$$

we have

$$
f(u)=\lambda u-\mu v \quad \text { and } \quad f(v)=\mu u+\lambda v
$$

from which we immediately obtain

$$
f_{\mathbb{C}}(u-i v)=(\lambda-i \mu)(u-i v)
$$

which shows that $\bar{w}=u-i v$ is an eigenvector of $f_{\mathbb{C}}$ for $\bar{z}=\lambda-i \mu$. Using this fact, we can prove the following lemma.

Lemma 1.1.8 Given a Euclidean space E, for any normal linear map $f: E \rightarrow E$, if $w=u+i v$ is an eigenvector of $f_{\mathbb{C}}$ associated with the eigenvalue $z=\lambda+i \mu$ (where $u, v \in E$ and $\lambda, \mu \in \mathbb{R}$ ), if $\mu \neq 0$ (i.e., $z$ is not real) then $\langle u, v\rangle=0$ and $\langle u, u\rangle=\langle v, v\rangle$, which implies that $u$ and $v$ are linearly independent, and if $W$ is the subspace spanned by $u$ and $v$, then $f(W)=W$ and $f^{*}(W)=W$. Furthermore, with respect to the (orthogonal) basis $(u, v)$, the restriction of $f$ to $W$ has the matrix

$$
\left(\begin{array}{cc}
\lambda & \mu \\
-\mu & \lambda
\end{array}\right) .
$$

If $\mu=0$, then $\lambda$ is a real eigenvalue of $f$ and either $u$ or $v$ is an eigenvector of $f$ for $\lambda$. If $W$ is the subspace spanned by $u$ if $u \neq 0$, or spanned by $v \neq 0$ if $u=0$, then $f(W) \subseteq W$ and $f^{*}(W) \subseteq W$.

If $f$ is a normal linear map, the proof of Lemma 1.1.8 shows that $\lambda, \mu, u$, and $v$, satisfy the equations

$$
\begin{aligned}
f(u) & =\lambda u-\mu v \\
f(v) & =\mu u+\lambda v \\
f^{*}(u) & =\lambda u+\mu v \\
f^{*}(v) & =-\mu u+\lambda v
\end{aligned}
$$

From the above, it is easy to see that $\lambda$ is an eigenvalue of $1 / 2\left(f+f^{*}\right)$, that $-\mu^{2}$ is an eigenvalue of $\left(1 / 2\left(f-f^{*}\right)\right)^{2}$, and that $u$ and $v$ are both eigenvectors of $1 / 2\left(f+f^{*}\right)$ for $\lambda$ and of $\left(1 / 2\left(f-f^{*}\right)\right)^{2}$ for $-\mu^{2}$.

It is easily verified that $1 / 2\left(f+f^{*}\right)$ and $\left(1 / 2\left(f-f^{*}\right)\right)^{2}$ are self-adjoint.

We can finally prove our first main theorem.

Theorem 1.1.9 Given a Euclidean space $E$ of dimension $n$, for every normal linear map $f: E \rightarrow E$, there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ such that the matrix of $f$ w.r.t. this basis is a block diagonal matrix of the form

$$
\left(\begin{array}{cccc}
A_{1} & & \ldots & \\
& A_{2} & \cdots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \cdots & A_{p}
\end{array}\right)
$$

such that each block $A_{i}$ is either a one-dimensional matrix (i.e., a real scalar) or a two-dimensional matrix of the form

$$
A_{i}=\left(\begin{array}{cc}
\lambda_{i} & -\mu_{i} \\
\mu_{i} & \lambda_{i}
\end{array}\right)
$$

where $\lambda_{i}, \mu_{i} \in \mathbb{R}$, with $\mu_{i}>0$.

After this relatively hard work, we can easily obtain some nice normal forms for the matrices of self-adjoint, skew self-adjoint, and orthogonal, linear maps.

However, for the sake of completeness (and since we have all the tools to so do), we go back to the case of a Hermitian space and show that normal linear maps can be diagonalized with respect to an orthonormal basis.

Theorem 1.1.10 Given a Hermitian space $E$ of dimension $n$, for every normal linear map $f: E \rightarrow E$, there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ of eigenvectors of $f$ such that the matrix of $f$ w.r.t. this basis is a diagonal matrix

$$
\left(\begin{array}{cccc}
\lambda_{1} & & \ldots & \\
& \lambda_{2} & \ldots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \ldots & \lambda_{n}
\end{array}\right)
$$

where $\lambda_{i} \in \mathbb{C}$.

Remark: There is a converse to Theorem 1.1.10, namely, if there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ of eigenvectors of $f$, then $f$ is normal. We leave the easy proof as an exercise.

### 1.2 Self-Adjoint, Skew Self-Adjoint, and Orthogonal Linear Maps

We begin with self-adjoint maps.
Theorem 1.2.1 Given a Euclidean space $E$ of dimension $n$, for every self-adjoint linear map $f: E \rightarrow E$, there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ of eigenvectors of $f$ such that the matrix of $f$ w.r.t. this basis is a diagonal matrix

$$
\left(\begin{array}{cccc}
\lambda_{1} & & \ldots & \\
& \lambda_{2} & \ldots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \ldots & \lambda_{n}
\end{array}\right)
$$

where $\lambda_{i} \in \mathbb{R}$.

Theorem 1.2.1 implies that if $\lambda_{1}, \ldots, \lambda_{p}$ are the distinct real eigenvalues of $f$ and $E_{i}$ is the eigenspace associated with $\lambda_{i}$, then

$$
E=E_{1} \oplus \cdots \oplus E_{p}
$$

where $E_{i}$ and $E_{j}$ are othogonal for all $i \neq j$.
Next, we consider skew self-adjoint maps.

Theorem 1.2.2 Given a Euclidean space $E$ of dimension n, for every skew self-adjoint linear map $f: E \rightarrow E$, there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ such that the matrix of $f$ w.r.t. this basis is a block diagonal matrix of the form

$$
\left(\begin{array}{cccc}
A_{1} & & \cdots & \\
& A_{2} & \cdots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \cdots & A_{p}
\end{array}\right)
$$

such that each block $A_{i}$ is either 0 or a two-dimensional matrix of the form

$$
A_{i}=\left(\begin{array}{cc}
0 & -\mu_{i} \\
\mu_{i} & 0
\end{array}\right)
$$

where $\mu_{i} \in \mathbb{R}$, with $\mu_{i}>0$. In particular, the eigenvalues of $f_{\mathbb{C}}$ are pure imaginary of the form $i \mu_{i}$, or 0 .

Remark: One will note that if $f$ is skew self-adjoint, then $i f_{\mathbb{C}}$ is self-adjoint w.r.t. $\langle-,-\rangle_{\mathbb{C}}$.

By Lemma 1.1.6, the map $i f_{\mathbb{C}}$ has real eigenvalues, which implies that the eigenvalues of $f_{\mathbb{C}}$ are pure imaginary or 0 .

Finally, we consider orthogonal linear maps.
Theorem 1.2.3 Given a Euclidean space $E$ of dimension n, for every orthogonal linear map $f: E \rightarrow E$, there is an orthonormal basis $\left(e_{1}, \ldots, e_{n}\right)$ such that the matrix of $f$ w.r.t. this basis is a block diagonal matrix of the form

$$
\left(\begin{array}{cccc}
A_{1} & & \cdots & \\
& A_{2} & \cdots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \cdots & A_{p}
\end{array}\right)
$$

such that each block $A_{i}$ is either 1, -1 , or a twodimensional matrix of the form

$$
A_{i}=\left(\begin{array}{cc}
\cos \theta_{i} & -\sin \theta_{i} \\
\sin \theta_{i} & \cos \theta_{i}
\end{array}\right)
$$

where $0<\theta_{i}<\pi$.

In particular, the eigenvalues of $f_{\mathbb{C}}$ are of the form $\cos \theta_{i} \pm i \sin \theta_{i}$, or 1 , or -1 .

It is obvious that we can reorder the orthonormal basis of eigenvectors given by Theorem 1.2.3, so that the matrix of $f$ w.r.t. this basis is a block diagonal matrix of the form

$$
\left(\begin{array}{ccccc}
I_{p} & & & \cdots & \\
& -I_{q} & & & \\
& & A_{1} & \cdots & \\
\vdots & & \vdots & \ddots & \vdots \\
& & & \cdots & A_{r}
\end{array}\right)
$$

where each block $A_{i}$ is a two-dimensional rotation matrix $A_{i} \neq \pm I_{2}$ of the form

$$
A_{i}=\left(\begin{array}{cc}
\cos \theta_{i} & -\sin \theta_{i} \\
\sin \theta_{i} & \cos \theta_{i}
\end{array}\right)
$$

with $0<\theta_{i}<\pi$.
The linear map $f$ has an eigenspace $E(1, f)=\operatorname{Ker}(f-\mathrm{id})$ of dimension $p$ for the eigenvalue 1 , and an eigenspace $E(-1, f)=\operatorname{Ker}(f+\mathrm{id})$ of dimension $q$ for the eigenvalue -1 .

If $\operatorname{det}(f)=+1(f$ is a rotation), the dimension $q$ of $E(-1, f)$ must be even, and the entries in $-I_{q}$ can be paired to form two-dimensional blocks, if we wish.

Remark: Theorem 1.2.3 can be used to prove a sharper version of the Cartan-Dieudonné Theorem.

Theorem 1.2.4 Let $E$ be a Euclidean space of dimension $n \geq 2$. For every isometry $f \in \mathbf{O}(E)$, if $p=\operatorname{dim}(E(1, f))=\operatorname{dim}(\operatorname{Ker}(f-\mathrm{id}))$, then $f$ is the composition of $n-p$ reflections and $n-p$ is minimal.

The theorems of this section and of the previous section can be immediately applied to matrices.

### 1.3 Normal, Symmetric, Skew Symmetric, Orthogonal, Hermitian, Skew Hermitian, and Unitary Matrices

First, we consider real matrices.
Definition 1.3.1 Given a real $m \times n$ matrix $A$, the transpose $A^{\top}$ of $A$ is the $n \times m$ matrix $A^{\top}=\left(a_{i, j}^{\top}\right)$ defined such that

$$
a_{i, j}^{\top}=a_{j, i}
$$

for all $i, j, 1 \leq i \leq m, 1 \leq j \leq n$. A real $n \times n$ matrix $A$ is

1. normal iff

$$
A A^{\top}=A^{\top} A
$$

2. symmetric iff

$$
A^{\top}=A
$$

3. skew symmetric iff

$$
A^{\top}=-A
$$

4. orthogonal iff

$$
A A^{\top}=A^{\top} A=I_{n}
$$

Theorems 1.1.9 and 1.2.1-1.2.3 can be restated as follows.

Theorem 1.3.2 For every normal matrix $A$, there is an orthogonal matrix $P$ and a block diagonal matrix $D$ such that $A=P D P^{\top}$, where $D$ is of the form

$$
D=\left(\begin{array}{cccc}
D_{1} & & \ldots & \\
& D_{2} & \ldots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \ldots & D_{p}
\end{array}\right)
$$

such that each block $D_{i}$ is either a one-dimensional matrix (i.e., a real scalar) or a two-dimensional matrix of the form

$$
D_{i}=\left(\begin{array}{cc}
\lambda_{i} & -\mu_{i} \\
\mu_{i} & \lambda_{i}
\end{array}\right)
$$

where $\lambda_{i}, \mu_{i} \in \mathbb{R}$, with $\mu_{i}>0$.

Theorem 1.3.3 For every symmetric matrix $A$, there is an orthogonal matrix $P$ and a diagonal matrix $D$ such that $A=P D P^{\top}$, where $D$ is of the form

$$
D=\left(\begin{array}{cccc}
\lambda_{1} & & \ldots & \\
& \lambda_{2} & \ldots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \ldots & \lambda_{n}
\end{array}\right)
$$

where $\lambda_{i} \in \mathbb{R}$.

Theorem 1.3.4 For every skew symmetric matrix $A$, there is an orthogonal matrix $P$ and a block diagonal matrix $D$ such that $A=P D P^{\top}$, where $D$ is of the form

$$
D=\left(\begin{array}{cccc}
D_{1} & & \ldots & \\
& D_{2} & \ldots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \ldots & D_{p}
\end{array}\right)
$$

such that each block $D_{i}$ is either 0 or a two-dimensional matrix of the form

$$
D_{i}=\left(\begin{array}{cc}
0 & -\mu_{i} \\
\mu_{i} & 0
\end{array}\right)
$$

where $\mu_{i} \in \mathbb{R}$, with $\mu_{i}>0$. In particular, the eigenvalues of $A$ are pure imaginary of the form $i \mu_{i}$, or 0 .

Theorem 1.3.5 For every orthogonal matrix $A$, there is an orthogonal matrix $P$ and a block diagonal matrix $D$ such that $A=P D P^{\top}$, where $D$ is of the form

$$
D=\left(\begin{array}{cccc}
D_{1} & & \ldots & \\
& D_{2} & \cdots & \\
\vdots & \vdots & \ddots & \vdots \\
& & \cdots & D_{p}
\end{array}\right)
$$

such that each block $D_{i}$ is either 1, -1 , or a twodimensional matrix of the form

$$
D_{i}=\left(\begin{array}{cc}
\cos \theta_{i} & -\sin \theta_{i} \\
\sin \theta_{i} & \cos \theta_{i}
\end{array}\right)
$$

where $0<\theta_{i}<\pi$.
In particular, the eigenvalues of $A$ are of the form $\cos \theta_{i} \pm i \sin \theta_{i}$, or 1 , or -1 .

We now consider complex matrices.

Definition 1.3.6 Given a complex $m \times n$ matrix $A$, the transpose $A^{\top}$ of $A$ is the $n \times m$ matrix $A^{\top}=\left(a_{i, j}^{\top}\right)$ defined such that

$$
a_{i, j}^{\top}=a_{j, i}
$$

for all $i, j, 1 \leq i \leq m, 1 \leq j \leq n$. The conjugate $\bar{A}$ of $A$ is the $m \times n$ matrix $\bar{A}=\left(b_{i, j}\right)$ defined such that

$$
b_{i, j}=\bar{a}_{i, j}
$$

for all $i, j, 1 \leq i \leq m, 1 \leq j \leq n$. Given an $n \times n$ complex matrix $A$, the adjoint $A^{*}$ of $A$ is the matrix defined such that

$$
A^{*}=\overline{\left(A^{\top}\right)}=(\bar{A})^{\top}
$$

A complex $n \times n$ matrix $A$ is

1. normal iff

$$
A A^{*}=A^{*} A
$$

2. Hermitian iff

$$
A^{*}=A
$$

3. skew Hermitian iff

$$
A^{*}=-A
$$

4. unitary iff

$$
A A^{*}=A^{*} A=I_{n}
$$

Theorem 1.1.10 can be restated in terms of matrices as follows. We can also say a little more about eigenvalues (easy exercise left to the reader).

Theorem 1.3.7 For every complex normal matrix $A$, there is a unitary matrix $U$ and a diagonal matrix $D$ such that $A=U D U^{*}$. Furthermore, if $A$ is Hermitian, $D$ is a real matrix, if $A$ is skew Hermitian, then the entries in $D$ are pure imaginary or null, and if $A$ is unitary, then the entries in $D$ have absolute value 1.
